## 1 Binary Search and Ternary Search

### 1.1 LowerBound

```

#include <bits/stdc++.h>
#include <ext/pb_ds/assoc_container.hpp>
#include <ext/pb_ds/tree_policy.hpp>
using namespace std;
using namespace __gnu_pbds;

template <class T>
using ordered_set = tree<T, null_type, less<T>,
    rb_tree_tag, tree_order_statistics_node_update>;

#define int long long int
#define pb push_back
#define pi pair<int, int>
#define pii pair<pi, int>
#define fir first
#define sec second
#define DEBUG 0
#define MAXN 1000001
#define mod 1000000007
// first element >= x
vector<int> k(MAXN);
int lower(int l, int r, int x) // first element >= x
{
    while (l < r)
    {
        int mid = (l + r) >> 1;
        (x <= k[mid]) ? r = mid : l = mid + 1;
    }
    return k[l];
}

```

## 1.2 Applications

```

#include <bits/stdc++.h>
using namespace std;

#define lli long long int
#define pb push_back
#define in insert
#define pi pair<int, int>
#define pii pair<int, pi>
#define mp make_pair
#define fir first
#define sec second
#define MAXN 1001

// 1 - ts para double
long double ts()
{
    long double l = 0, r = DBL_MAX;
    for (int i = 0; i < 2000; i++)
    {
        long double l1 = (l * 2 + r) / 3.0;
        long double l2 = (l + 2 * r) / 3.0;
        if (possible(l1))
            r = l2;
        else
            l = l1;
    }
    return l;
}

// 2- bb para double
long double bb()
{
    long double i = 0, f = DBL_MAX, m;
    while (f - i > 0.000000001)
    {
        m = (i + f) / 2.0;
        if (possible(m))
            f = m;
        else
            i = m;
    }
    return i;
}

// 3 - bb pra int
lli bb()
{
    lli i = 0, f = INT_MAX, m;
    while (i < f)

```

```

{
    m = (i + f) / 2;
    if (possible(m))
        f = m;
    else
        i = m + 1;
}
return i;
}
// 4 - ts pra int (valor minimo da funcao f(x)), sendo x
// um inteiro
int l = 1, r = INT_MAX;
while (r - l > 15)
{
    int l1 = (l * 2 + r) / 3;
    int l2 = (l + 2 * r) / 3;

}
for (int i = 1; i <= r; i++)
// vejo qual a melhor opcao de l ate r em o(n)

// busca ternaria para int, usando busca binaria:
int l = 0, r = 1e9;
while (l < r)
{
    int mid = (l + r) >> 1;
    (calc(mid) < calc(mid + 1)) ? r = mid : l = mid + 1;
}
return calc(l);

```

### 1.3 TS

```

// busca ternaria
// divide em 3 partes, 2 mids
// mid1 = l + (r-l)/3
// mid2 = r - (r-l)/3
#include <bits/stdc++.h>
using namespace std;

```

```

#define lli long long int
#define pb push_back
#define in insert
#define pi pair<int, int>
#define pii pair<int, pi>
#define mp make_pair
#define fir first
#define sec second
#define MAXL 100001

```

```

int n, key;
vector<int> ar;

int ts()
{
    int l = 0, r = n - 1;
    while (r >= l)
    {
        int mid1 = l + (r - l) / 3;
        int mid2 = r - (r - l) / 3;
        if (ar[mid1] == key)
            return mid1;
        if (ar[mid2] == key)
            return mid2;
        if (key < ar[mid1])
            r = mid1 - 1;
        else if (key > ar[mid2])
            l = mid2 + 1;
        else
        {
            l = mid1 + 1;
            r = mid2 - 1;
        }
    }
    return -1; // nao encontrado
}

signed main()
{
    ios_base::sync_with_stdio(false);
    cin.tie(NULL);
    cin >> n;
    ar.resize(n);
    for (int i = 0; i < n; i++)
        cin >> ar[i];
    sort(ar.begin(), ar.end());
    cin >> key;
    cout << ts() << endl;
    return 0;
}

```

### 1.4 UpperBound

```

#include <bits/stdc++.h>
#include <ext/pb_ds/assoc_container.hpp>
#include <ext/pb_ds/tree_policy.hpp>
using namespace std;
using namespace __gnu_pbds;

template <class T>

```

```
using ordered_set = tree<T, null_type, less<T>,
    rb_tree_tag, tree_order_statistics_node_update>;
```

```
#define int long long int
#define pb push_back
#define pi pair<int, int>
#define pii pair<pi, int>
#define fir first
#define sec second
#define DEBUG 0
#define MAXN 1000001
#define mod 1000000007
// last element <= x
vector<int> k(MAXN);
int upper(int l, int r, int x)
{
    while (l < r)
    {
        int mid = (l + r + 1) >> 1;
        (k[mid] <= x) ? l = mid : r = mid - 1;
    }
    return k[l];
}
```

## 1.5 STL

```
// lower - primeiro maior ou igual a x
// upper - ultimo menor ou igual a x
```

```
#include <bits/stdc++.h>
using namespace std;

#define lli long long int
#define pb push_back

vector<int> v ;
int main()
{
    int n , aux ;
    cin >> n ;

    for (int i = 0 ; i < n ; i++)
    {
        cin >> aux ;
        v.pb(aux);
    }

    sort(v.begin() , v.end());

    int q ;
```

```
cin >> q ;

while (q-->0)
{
    cin >> aux ;
    vector<int> :: iterator low = lower_bound (v.
        begin() , v.end() , aux) ;
    vector<int> :: iterator up = upper_bound (v.
        begin() , v.end() , aux) ;

    cout << (low - v.begin()) << " " << (up - v.
        begin()) - 1 << endl ;
}

return 0 ;
}
```

## 1.6 BS

```
#include <bits/stdc++.h>
using namespace std ;

#define lli long long int
#define pb push_back

vector<int> v;
int binarysearch (int n , int x)
{
    int i = 0 ;
    int f = n - 1 ;
    int m ;

    while(i <= f)
    {
        m = (i + f) / 2 ;

        if(v[m] == x) return m + 1 ;
        if(v[m] < x) i = m + 1 ;
        if(v[m] > x) f = m - 1 ;
    }

    return 0 ;
}

int main ()
{
    int n , aux , m ;

    cin >> n ;

    for (int i = 0 ; i < n ; i++)
```

```

{
    cin >> aux ;
    v.pb(aux);
}

sort(v.begin() , v.end());

cin >> m ;
cout << binarysearch(n , m) << endl ;

return 0 ;
}

```

## 2 Miscellaneous

### 2.1 meetinthemiddle

```

#include <bits/stdc++.h>

// Given an array of n integers, Let's say that a
// segment of this array is good
// if the difference between the maximum and minimum
// elements on this segment is at most k
// Your task is to find the number of different good
// segments
// amazing trick using stack

```

## 2.5 inversion count

```

// seja S = a1, a2 , ... , an
// uma inversao S e um par (i,j) com i < j e ai > aj

// Solucao O(n2) nao ideal:
//for(int i=0;i<n;i++)
//    for(int j=i+1;j<n;j++)
//        if(v[i]>v[j]) ans++;

// Em vez de trabalharmos com o vetor inteiro(n2), vamos
// dividir o vetor ao meio e trabalhar com suas
// metades,
// que chamaremos de u1 e u2.

// Queremos saber o valor de inv, o numero de inversoes
// em v. Ha tres tipos de inversoes (i,j) (i,j) em v:
// aquelas em que i e j estao ambos em u1, aquelas em
// que i e j estao ambos em u2 e aquelas
// em que i esta em u1 e j esta em u2.
#include <bits/stdc++.h>

    return 0;
}

/*
game theory (um exemplo simples de problema pra ficar no
repo)

```

- pro nim classico
- existem n pilhas cada uma possui  $x[i]$  blocos
- em uma play posso escolher uma pilha e tirar uma quantidade qualquer de blocos dela
- quem ganha?
- o jogador que começa ganha se o xor dos tamanhos das pilhas for  $\neq 0$

- teorema sprague-grundy (transformar um jogo qualquer em nim)
- seja  $v$  um estado que eu tou do jogo, podemos calcular o Grundy number desse estado
- seja o conjunto de estados adjacentes a  $v$   $\{u_1, u_2, \dots, u_n\}$
- $g(v) = \text{mex}(g(u_1), g(u_2), \dots, g(u_n))$
- se  $v$  não tem nenhum estado adjacente, então  $g(v) = 0$
- $g(v) \rightarrow$  Grundy number do estado  $v$
- com isso se tivermos vários estados iniciais (várias pilhas)
- podemos simplesmente achar o Grundy number de cada um deles e depois saber quem ganha
- pelo valor do xor dos Grundy numbers

  

- exemplo: floor division game
- existem  $n$  números e em uma play posso escolher um deles e dividir por 2, 3, 4, 5 ou 6
- quem ganha?
- achar o Grundy number de cada um dos  $n$  números
- se o xor for  $\neq 0$ , ganha quem começa jogando
- caso contrário, o outro jogador ganha

  

- as vzs e util tbm ver se existe um padrão (em caso de altas constantes)
- notando o padrão, dá pra achar o Grundy number de forma mais eficiente e resolver o problema

\*/

## 2.7 stack trick

```
#include <bits/stdc++.h>
using namespace std;

#define PI acos(-1)
#define int long long int
#define pb push_back
#define pi pair<int, int>
#define fir first
#define sec second
#define MAXN 300001
#define mod 1000000007

int n;
vector<int> v;
vector<int> ans;

void solve()
{
    stack<pi> s;
```

```
for (int i = n - 1; i >= 0; i--)
{
    while (!s.empty() && s.top().fir <= v[i])
        s.pop();
    (!s.empty()) ? ans[i] = s.top().sec : ans[i] = -1;
    s.push({v[i], i});
}

signed main()
{
    ios_base::sync_with_stdio(false);
    cin.tie(NULL);
    cin >> n;
    v.resize(n);
    ans.resize(n);
    for (int i = 0; i < n; i++)
        cin >> v[i];
    solve();
    for (auto const &i : ans)
        cout << i << " ";
    cout << endl;
}

// WITHOUT SEGMENT TREE
// for each index (0 <= i < n), find another index (0 <=
// j < n)
// which v[j] > v[i] and j > i and j is as close as
// possible to i.
// if this index does not exist, print -1

/*
5
1 3 3 4 5
*/
/*
1 3 3 4 -1
*/
```

## 3 STL

### 3.1 ordered set

```
#include <bits/stdc++.h>
#include <ext/pb_ds/assoc_container.hpp>
#include <ext/pb_ds/tree_policy.hpp>
using namespace std;
using namespace __gnu_pbds;

#define int long long int
#define pb push_back
```

```

#define pi pair<int, int>
#define pii pair<pi, int>
#define fir first
#define sec second
#define DEBUG false
#define MAXN 200002

template <class T> // template do ordered set
using ordered_set = tree<T, null_type, less<T>,
    rb_tree_tag, tree_order_statistics_node_update>;

signed main()
{
    ios_base::sync_with_stdio(false);
    cin.tie(NULL);
    ordered_set<int> s; // ordered_set
    s.insert(1);
    s.insert(1);
    s.insert(2);
    s.insert(4);
    s.insert(3);
    for (auto const &i : s) // nao adiciona elementos
        repetidos, que nem o set normal
        cout << i << " ";
    cout << endl;
    cout << *(s.find_by_order(0)) << endl; // iterator do
        elemento 0
    cout << *(s.find_by_order(1)) << endl; // iterator do
        elemento 1
    cout << s.order_of_key(4) << endl; // quantidade
        de elementos que sao menores do que 4
    cout << s.order_of_key(6) << endl; // quantidade
        de elementos que sao menores do que 4
}
// find_by_order : O(log n), retorna (um iterator) qual
// o k-esimo elemento do set
// order_of_key: O(log n), retorna qual a quantidade de
// elementos menores do que x no set

```

## 3.2 STL

### 1) Vector

```

vector <int> v; //Criacao o vector

v.push_back(10); //Adiciono o elemento 10 no final do
    vector v
v.size() // retorna o tamanho do vector
v.resize(10); //Muda o tamanho do vector v para 10.
v.pop_back(); //Apaga o ultimo elemento do vector V.

```

```

v.clear(); // apaga todos os elementos do vector v .
sort(v.begin(), v.end()); //Ordena todo o vector v

```

### 2) Pair

```

pair <string, int> p; // criando a pair relacionando um
    first com um second

```

```

p.first = "Joao"; // adicionando elementos
p.second = 8 ; //adicionando elementos

```

```

// utilidade: vector de pair
vector< pair <int, string> > v; // criando o vector v de
    pair
v.push_back(make_pair(a,b)); // dando push back em uma
    pair no vector usando make_pair
sort(v.begin(), v.end()); // tambem e possivel ordenar o
    vector de pair

```

### 3) Queue / Fila

```

queue <int> f; // criando a queue

```

```

f.push(10); // adiciona alguem na fila
f.pop(); // remove o elemento que esta na frente da fila
f.front(); // olha qual o elemento esta na frete da fila
f.empty() // retorna true se a fila estiver vazia e
    false se nao estiver vazia

```

### 4) Stack / Pilha

```

stack <int> p ; // criando a stack

```

```

pilha.push(x); //Adiciona o elemento x no topo da pilha
pilha.pop(); //Remove elemento do topo da pilha
pilha.top(); // retorna o elemento do topo da pilha
pilha.empty(); // verifica se a pilha esta vazia ou nao

```

### 5) Set

```

set <int> s ; // criando a set
// obs: a set nao adiciona elementos repetidos

```

```

s.insert(10); //Adiciona o elemento 10 no set
s.find(10) // Para realizar uma busca no set utilizamos
    o comando find,
o find retorna um ponteiro que aponta para o elemento
    procurado caso o elemento esteja no set ou para o

```

```

    final do set, caso o elemento procurado nao esteja
    no set , em complexidade  $O(\log n)$ 

if(s.find(10) != s.end()) // procurando pelo 10, se ele
    estiver no set
s.erase(10); //Apaga o elemento 10 do set em  $O(\log n)$ 
s.clear(); // Apaga todos os elementos
s.size(); // Retorna a quantidade de elementos
s.begin(); // Retorna um ponteiro para o inicio do set
s.end(); // Retorna um ponteiro para o final do set

6)Map
map <string, int> m; //Cria uma variavel do tipo map que
    mapeia strings em int
// Em um map cada elemento esta diretamente ligado a um
    valor, ou seja, cada elemento armazenado no map
    possui um valor correspondente
// Se tivermos um map de strings em inteiros e inserimos
    os pair ("Joao", 1), ("Alana", 10), ("Rodrigo", 9)
// Caso facamos uma busca pela chave "Alana" receberemos
    o numero 10 como retorno.

m.insert(make_pair("Alana", 10)); //Inserimos uma
    variavel do tipo pair diretamente no map,  $O(\log n)$ 
M["Alana"] = 10; //Relacionando o valor 10 a chave "
    Alana"
if(m.find("Alana") != m.end()){ //Se a chave "Alana" foi
    inserida no map
cout << m["Alana"] << endl; //Imprime o valor
    correspondente a chave "Alana", no caso, o valor 10.
m.erase("Alana"); //Apaga o elemento que possui a chave
    "Alana" do map
m.clear(); // Apaga todos os elementos
m.size(); // Retorna a quantidade de elementos
m.begin(); // Retorna um ponteiro para o inicio do map
m.end(); // Retorna um ponteiro para o final do map

7)Priority Queue
priority_queue <int> q; // declarando a priority queue
// Para utilizar a priority_queue do C++ e importante
    apenas saber que o maior elemento sempre estara na
    primeiro posicao.
// Com execucao disso, todos os outros metodos sao
    semelhantes ao uso de uma queue comum, porem para
    manter a estrutura organizada, a complexidade da
    operacao de insercao e  $O(\log n)$ .
p.push(i) // adiciono o elemento i na priority_queue
p.pop(); // apago o primeiro da fila

```

```
p.top(); // vejo quem esta no topo
```

## 4 Utils

### 4.1 runner2

```

# This script does the following:
# 1 - Run a code with all inputs files from a folder
# 2 - Compare the output for each test case with the
    answer
import os

code = "a.cpp" # Path to your code
input_folder = "input" # Path to folder which the input
    files are
output_folder = "output" # Path to folder which the
    output files are
input_prefix = "L_" # prefix of all input files names
output_prefix = "L_" # prefix of all input files names
tests = 56 # Number of test cases

def compile_code():
    os.system('g++ ' + code + ' -o code -O2')

// eliminacao gaussiana
// para resolver sistemas com n equacoes e m incognitas

// para isso iremos utilizar uma representacao usando
// matrizes, no qual uma coluna extra e adicionada,
// representando os resultados de cada equacao.

// algoritmo:
// ideia: qualquer equacao pode ser reescrita como uma
// combinacao linear dela mesma
// 1- dividir a primeira linha(primeira equacao) por a
// [0][0]
// 2- adicionar a primeira linha as linhas restantes, de
// modo que, os
// coeficientes da primeira coluna se tornem todos
// zeros, para que
// isso aconteca, na i-esima linha devemos adicionar
// a primeira linha
// multiplicada por (a[i][0] * -1)
// 3- com isso, o elemento a[0][0] = 1 e os demais
// elementos da primeira coluna
// serao iguais a zero
// 4- continuamos o algoritmo a partir da etapa 1

```

```

    novamente, dessa vez
    // com a segunda coluna e a segunda linha, dividindo
    // a linha por a[1][1]
    // e assim sucessivamente
    // 5- ao final, teremos a resposta

    // complexidade  $O(\min(n, m) * n * m)$ ;
    // se  $n == m$ , logo a complexidade sera  $O(n^3)$

// multiplicar dois polinomios A e B
// basic approach:
// aplicar a propriedade distributiva e fazer essa
// multiplicacao em O(N^2)
// porem podemos melhorar
// vamos la
// 1 - todo polinomio de grau d que e representado na
// forma de coeficientes
// de coeficientes possui uma representacao em
// forma de d - 1 pontos
// 2 - para esse conjunto de pontos, so existe um unico
// polinomio equivalente
// 3 - DFT -> transformacao da representacao de
// coeficientes para representacao
// de pontos
// 4 - com isso, para multiplicar os dois polinomios
// agora basta multiplicar
// os conjuntos de pontos e com isso obtemos a
// representacao usando pontos
// do polinomio resultante
// 5 - DFT(A * B) = DFT(A) * DFT(B);
// 6 - porem agora precisamos transformar a resposta
// obtida na multiplicacao dos pontos
// para a representacao em que usa os coeficientes
// 7 - inverseDFT -> transformacao da representacao de
// pontos para representacao
// de coeficientes
// 8 - A * B = inverseDFT(DFT(A) * DFT(B))
// 9 - FFT -> metodo para computar a DFT em O(N * log(N))
// 10 - iremos usar divide and conquer para isso, vamos
// splitar o polinomio

```

```

// atual em 2 polinomios de grau ((n / 2) - 1), tal
// que, a soma deles
// resulte no polinomio que tinhamos antes
// 11 - agora para achar a inverseDFT de uma DFT, iremos
// escrever a DFT
// em forma de matriz, essa matriz e chamada de
// matriz de vandermonde
// e em geral, podemos escrever a resposta como uma
// multiplicacao de
// matrizes
// 12 - essa multiplicacao de matrizes pode ser descrita
// como:
// a^-1 * b = c
// no qual:
// a^-1 -> inversa da matriz a(DFT)
// b -> valores dos coeficientes do polinomio A
// c -> valores dos coeficientes da resposta

```

    // resposta = ncr(n - 1, k - 1)

    // problema exemplo:
    // https://codeforces.com/contest/451/problem/E
    // contar quantas k-tuplas com soma == n
    // tal que: x[i] >= 0 e x[i] <= f[i]
    // k <= 20

    // solucao:
    // conta tudo com stars and bars
    // dai preciso subtrair todas as possibilidades
    // invalidas (com pelo menos um i tal que x[i] > f[i])
    // seja n(i) as possibilidades com x[i] > f[i]
    // dai eu quero calcular a quantidade de elementos na
    // uniao entre todos os n(i)
    // dai da pra fzr usando a formulinha de uniao de
    // conjuntos:
    // n(A uniao B uniao C) = n(A) + n(B) + n(C) - n(A
    // intersecao B) ... + n(A intersecao B intersecao C)
    // itera por todos os 2^n subsets e calcula o que deve
    // subtrair/somar com aqueles caras

```

// hash de arvores
// para descobrir se duas arvores sao isomorficas

// 1 - achar todos os centroides da arvore (toda arvore
//      tem no maximo 2 centroides)
// 2 - achar o hashing com a arvore enraizada em cada
//      centroid
// 3 - dai o hashing da arvore eh um pair ordenado,
//      indicando o hashing de cada enraizamento no centroid

```

// euler tour of a tree
// muito util para algumas coisas
// exemplos:
// 1- soma da subarvore de v (com update)
// usando segment trees, podemos fazer uma query(entrei[
v], sai[v])
// 2- LCA
// lca(u, v) = query(entrei[u], entrei[v])
// usando uma query de minimo e considerando as
// profundidade dos vertices
// a resposta sera o vertice de profundidade minima que
// encontrarmos no intervalo
// 3- agilidade para remover arestas/vertices/subtrees
// da arvore
// basta apenas tratar o segmento equivalente do jeito
// que for necessario
// 4- reroot a tree
// basta apenas rotacionar o euler path

```

## 7.25 notes

### ## Bipartite Graph

A bipartite graph is a graph that does not contain any odd-length cycles.

### ## Directed acyclic graph (DAG)

Is a directed graph with no directed cycles.

### ## Independent Set

Is a set of vertices in a graph, no two of which are adjacent. That is, it is a set  $S$  of vertices such that for every two vertices in  $S$ , there is no edge connecting the two.

### ## Clique

Is a subset of vertices of an undirected graph such that every two distinct vertices in the clique are adjacent.

### ## Vertex Cover

Is a set of vertices that includes at least one endpoint of every edge of the graph.

### ## Edge Cover

Is a set of edges such that every vertex of the graph is incident to at least one edge of the set.

### ## Path Cover

Given a directed graph  $G = (V, E)$ , a path cover is a set of directed paths such that every vertex  $v$  belongs to at least one path.

### ## Koning's Theorem

In any bipartite graph, the number of edges in a maximum matching equals the number of vertices in a minimum vertex cover.

### ## Properties

- Every tree is a bipartite graph.
- Any  $N \times M$  grid is a bipartite graph.
- A set of vertices is a vertex cover if and only if its complement is an independent set.
- The number of vertices of a graph is equal to its minimum vertex cover number plus the size of a maximum independent set.
- In bipartite graphs, the size of the minimum edge cover is equal to the size of the maximum independent set
- In bipartite graphs, the size of the minimum edge cover plus the size of the minimum vertex cover is equal to the number of vertices.
- In bipartite graphs, maximum clique size is two.

### ## Min-cut

The smallest total weight of the edges which if removed would disconnect the source from the sink.

### ## Max-flow min-cut theorem

In a flow network, the maximum amount of flow passing from the source to the sink is equal to the total weight of the edges in a minimum cut.

### ## Maximum flow with vertex capacities

In other words, the amount of flow passing through a vertex cannot exceed its capacity. To find the maximum flow, we can transform the problem into the maximum flow problem by expanding the network. Each vertex  $v$  is replaced by  $v$ -in and  $v$ -out, where  $v$ -in

is connected by edges going into  $v$  and  $v$ -out is connected to edges coming out from  $v$ . Then assign capacity  $c(v)$  to the edge connecting  $v$ -in and  $v$ -out.

## ## Undirected edge-disjoint paths problem

We are given an undirected graph  $G = (V, E)$  and two vertices  $s$  and  $t$ , and we have to find the maximum number of edge-disjoint  $s$ - $t$  paths in  $G$ .

## ## Undirected vertex-disjoint paths problem

We are given an undirected graph  $G = (V, E)$  and two vertices  $s$  and  $t$ , and we have to find the maximum number of vertex-disjoint (except for  $s$  and  $t$ ) paths in  $G$ .

## ## Menger's theorem

The maximum number of edge-disjoint  $s$ - $t$  paths in an undirected graph is equal to the minimum number of edges in an  $s$ - $t$  cut-set.

## ## Undirected vertex-disjoint paths solution

We can construct a network  $N=(V,E)$  from  $G$  with vertex capacities, where the capacities of all vertices and all edges are 1. Then the value of the maximum flow is equal to the maximum number of independent paths from  $s$  to  $t$ .

## ## Minimum vertex-disjoint path cover in directed acyclic graph (DAG)

Given a directed acyclic graph  $G=(V, E)$ , we are to find the minimum number of vertex-disjoint paths to cover each vertex in  $V$ . We can construct a bipartite graph  $G'$  from  $G$ . Each vertex  $v$  is replaced by  $v$ -in and  $v$ -out, where  $v$ -in is connected by edges going into  $v$  and  $v$ -out is connected to edges coming out from  $v$ . Then it can be shown that  $G'$  has a matching  $M$  of size  $m$  if and only if  $G$  has a vertex-disjoint path cover  $C$  of containing  $m$  edges and  $n-m$  paths.

## ## Minimum general path cover in directed acyclic graph (DAG)

A general path cover is a path cover where a vertex can belong to more than one path. A minimum general path cover may be smaller than a minimum vertex-disjoint

path cover. A minimum general path cover can be found almost like a minimum vertex-disjoint path cover. It suffices to add some new edges to the matching graph so that there is an edge  $a - b$  always when there is a path from  $a$  to  $b$  in the original graph.

## ## Dilworth's theorem

An antichain is a set of nodes of a graph such that there is no path from any node to another node using the edges of the graph. Dilworth's theorem states that in a directed acyclic graph, the size of a minimum general path cover equals the size of a maximum antichain.

## ## Hall's Theorem

Hall's theorem can be used to find out whether a bipartite graph has a matching that contains all left or right nodes. Assume that we want to find a matching that contains all left nodes. Let  $X$  be any set of left nodes and let  $f(X)$  be the set of their neighbors. According to Hall's theorem, a matching that contains all left nodes exists exactly when for each  $X$ , the condition  $|X| \leq |f(X)|$  holds.

## ## Extra (Getting Confidence Trick)

[2019-2020 ACM-ICPC Brazil Subregional Programming Contest, problem G] (<https://codeforces.com/gym/102346/problem/G>)

<p>If you need to maximize a number  $x = (a * b * c * \dots)$ , then you can write it as  $x = (e^{\log(a)} * e^{\log(b)} * e^{\log(c)} * \dots)$ , and then the number is  $x = e^{(\log(a) + \log(b) + \log(c) + \dots)}$ , and the problem now becomes a problem of maximizing the sum of  $(\log(a) + \log(b) + \log(c) + \dots)$ .</p>

Use `exp()` and `log()` C++ functions :)

## 7.26 caminhoeuleriano

```
// caminho euleriano em um grafo
// passa por todas as arestas apenas uma unica vez e
percorre todas elas
// condicao de existencia:
// todos os vertices possuem grau par (ciclo euleriano)
comeca e acaba no mesmo vertice
// ou
// apenas 2 vertices possuem grau impar, todos os outros
possuem grau par ou == 0.
// comece num vertice de grau impar e termina num
vertice de grau impar nesse caso.
// solucao:
// rodar um dfs com map de visited para as arestas
// no final por o source no vector path
// ao final teremos o caminho inverso no vector path
// note que o caminho inverso tambem e um caminho valido
```

### 7.31 centroid decomposition

```

// centroid de uma arvore -> e um no que ao ser removido
// da arvore, separaria as
// arvores resultantes de modo com que a maior arvore
// desse conjunto teria no maximo
// (n / 2) nos, sendo n o numero de nos da arvore. Para
// qualquer arvore com n nos,
// o centroid sempre existe.

//
// //////////////////////////////////////

```

```

// centroid decomposition -> muito util para tentar
// diminuir a complexidade em certos
// tipos de consultas a serem feitas, uma maneira melhor
// de organizar a arvore.

```

```

// algoritmo:
// 1) o centroid e a raiz dessa nova arvore
// 2) achar o centroid das arvores menores que surgiram
// com a remocao do centroid "pai"
// 3) por uma aresta entre o centroid "filho" e o
// centroid "pai"
// 4) repetir isso ate todos os nos serem removidos
// 5) ao final teremos a centroid tree

```

    }
}

```

```
    return 0;
}
```

## 7.34 Kruskal

```
// Algoritmo de kruskal - Achar a mst

// 1 - listar todas as arestas em ordem crescente.

// 2 - Cada aresta liga dois vertices x e y, checar se
// eles ja estao na mesma componente conexa
// (aqui, consideramos apenas as arestas ja colocadas na
// arvore).

// 3 - Se x e y estao na mesma componente, ignoramos a
// aresta e continuamos o procedimento
// (se a usassemos, formariamos um ciclo). Se estiverem
// em componentes distintas, colocamos a aresta
// na arvore e continuamos o procedimento.

// OBS: como a prioridade eh ordenar pelas menores
// distancias, basta botar o custo da aresta como
// first no vector das arestas para poder ordenar

// em suma: ordeno as arestas em ordem crescente com
// prioridade no custo, depois para cada aresta,
// se o find(x) != find(y) sendo x e y os vertices das
// arestas, eu adiciono eles a mst e dou um join
// nos dois, como as arestas tao ordenadas em ordem
// crescente, o primeiro que eu pego
// eh necessariamente a melhor opcao e assim a mst eh
// formada.

// https://cp-algorithms.com/string/suffix-automaton.
// html
// suffix automaton
// definicao: um suffix automaton de uma string s e um
// automato finito deterministico
// que aceita todos os suffixos da string s.
// ou seja:
// um suffix automaton eh um grafo aciclico orientado
// tal que, um vertice representa um estado
// e uma aresta representa uma transicao (um caractere a
// mais em relacao ao estado(suffixo) atual)
// t0 -> estado inicial(string vazia), e todos os demais
// estados podem ser alcançados a partir de t0
// o suffix automaton minimiza o numero de vertices

// a propriedade mais importante de um suffix automaton
// eh a de que
// ele contem informacoes sobre todas as substrings de s
// pois, qualquer caminho comecando do estado t0
// corresponde a uma substring de s

// conceitos:

```

```

// 1 - endpos
// seja t uma substring de s, endpos(t) eh o conjunto de
// todas os indices(posicoes)
// na string s no qual todas as ocorrencias de t acabam
// por exemplo, se s = "abcbc" e t = "bc"
// logo endpos(t) = {2, 4}
// com isso se duas substrings t1 e t2 possuem os
// seus endpos iguais,
// chamamos de endpos-equivalent e dai podemos extrair
// algumas informacoes
// info 1: se duas substrings u e w u.size() <= w.size()
// , se u eh um sufixo de w, logo endpos(u) esta
// contido em endpos(w)
// info 2: se duas substrings u e w u.size() <= w.size()
// , se u nao eh um sufixo de w, logo nao existe
// interseccao entre endpos(u) e endpos(w)

// 2 - suffix link
// seja v algum estado != t0, sabemos que v corresponde
// a classe de strings que possui os mesmos endpos
// seja w a maior dessas strings, com isso, todas as
// demais sao suffixos de w
// com isso um suffix_link(v) corresponde ao maior
// suffix de w que esta em outra classe de equivalencia
// pelos endpos
// com isso podemos abstrair algumas informacoes:
// info 1: os suffix links foram uma arvore enraizada em
// t0
// info 2: se construirmos uma arvore usando os sets
// endpos, a estrutura sera a arvore com os suffix
// links

// com isso, vamos ao algoritmo
// 1 - vai ser online, e iremos adicionar os caracteres
// de 1 por 1, da esquerda para a direita
// 2 - com isso para adicionar um novo char, seja v o
// ultimo estado que adicionamos antes do atual,
// adicionamos uma aresta
// do proximo em relacao a ele e iremos procurar pelo
// suffix link para adicionar
// 3 - complexidade O(n) ou O(n log k), se usarmos uma
// map para guardar as transicoes partindo de um estado

// exemplos de aplicacoes:

// 1 - checar se t aparece em s como substring:
// construa o suffix automaton de s, e vamos tentar
// fazer um caminho partindo de t0
// se em algum momento, nao existir transicao, logo nao

```

```

    existe
// se conseguir chegar no final, existe

// 2 - numero de substrings diferentes de s
// constura o suffix automaton de s, sabemos que, cada
// substring de s corresponde a um caminho no automato
// com isso, o numero de substrings distintas eh o
// numero de caminhos diferentes que comecam de t0
// e terminam em algum canto
// isso pode ser calculado facilmente com uma dpzinha

// 3 - tamanho total de todas as substrings distintas de
// s
// similar a solucao passada, podemos fazer isso com uma
// dpzinha :)

// 4 - a k-esima menor substring lexicografica
// a k-esima menor substring lexicograficamente
// corresponde ao k-esimo path no suffix automaton
// se considerarmos as transicoes sempre indo do menor
// char para o maior durante o percurso

// 5 - o menor cyclic shift
// construa o suffix automaton da string s + s (
// duplicada)
// com isso o suffix automaton vai conter todos os
// cyclic shifts da string s
// e agora o problema eh reduzido para: encontre o menor
// caminho lexicograficamente de tamanho s.size()

// 6 - numero de ocorrencias de uma substring t em s
// construa o suffix automaton da string s
// com isso, quando criamos um no que nao seja o t0 nem
// um clone
// inicializamos cnt[v] = 1
// depois vamos percorrer todo os estados em ordem
// decrescente de len
// e aplicando cnt[link(v)] += cnt[v]
// no final, para responder a query basta fazer o
// caminho ate o estado que quisermos e printar o cnt
// dele

// e mais uma porrada de aplicacoes alem dessas :)

// example of a problem: https://www.spoj.com/problems/SUBLEX/
// ver qual a k-th string lexicografica sem repeticao
// note que o k pode ser gigante
// ideia: calcular dp[v] -> quantidade de caminhos que
// comecam em v

```

```

// dai para cada query roda um dfs, sendo que, so vou
// pro proximo estado se at + dp[u] >= k
// caso contrario, posso ignorar

```

// kmp
// algoritmo eh online, vai coonstruindo da esquerda pra
// direita
// calcula pi[i], a seguinte funcao:
// seja a substring s.substr(0, i + 1)
// pi[i] = tamanho do maior prefixo que tbm eh um sufixo
// dessa substring

// dai por exemplo
// da pra contar a quantidade de matchings de s em t
// so concatenar as strings fazendo: t = s + "*" + t
// dai contar as posicoes com pi[i] = s.size()

// tambem eh possivel construir um automato do kmp
// do tipo
// se meu pi[i] == x, e leio a letra c
// dai devo ir pro estado p[i] == y
// as transicoes podem ser computadas e isso pode ser
// muito util

    cin >> s;
    manacher(s);
    return 0;
}

// algoritmo de manacher

// motivacao: dada uma string s, encontre todos os pares
// (l, r) tal que, a substring s[l,r]
// e palindroma.

// para cada posicao (0 <= i < s.size()), vamos
// encontrar os valores de dl[i] e d2[i],
// sendo estes o numero de palindromos com comprimentos
// impares e com comprimentos pares
// e com i sendo a posicao central desses palindromos

// algoritmo mais facil:
// para cada posicao (0 <= i < s.size()), ele tenta
// aumentar a resposta em 1
// ate q nao seja mais possivel
// while(s[i - curr] == s[i + curr])
// complexidade O(N^2)

// algoritmo de manacher:
// para cada posicao (0 <= i < s.size()):
// seja o par (l, r) os extremos da substring palindroma
// que possui o maior r entre todas as encontradas ate
// entao
// se i > r, o fim do ultimo palindromo foi antes de i:
// iremos rodar o algoritmo mais facil mais facil e ir
// ate o limite.
// caso contrario, so precisamos rodar o algoritmo a
// partir de onde nao foi percorrido previamente.
// ao final se o r atual e maior do que o nosso antigo r
// , atualizamos o par (l, r)
// por incrivel que pareca, a complexidade e O(N)

// voltando para a motivacao:
// se temos os valores de dl[i] e d2[i]:
// a substring s[i - k, i + k] e palindroma, para todo
// (0 <= k < dl[i])
// a substring s[i - k - 1, i + k] e palindroma, para
// todo (0 <= k < d2[i])
// dai temos todos os intervalos
```

```
// note que a complexidade do algoritmo de manacher e O
// (N),
// mas como a quantidade maxima de palindromos em uma
// string e n^2,
// imprimir todos os intervalos consequentemente teria
// complexidade O(N^2) no pior caso
```

// 1- poligono: uma figura plana que possui no minimo 3
//    lados e 3 angulos
// 2- poligono convexo: um poligono cujo todos os seus
//    angulos internos sao menores do que 180 graus

// convex hull:
// dados n pontos em um plano, o objetivo e achar o
//    menor poligono convexo que possui todos os n pontos
//    dados
// Graham's Scan, complexidade  $O(n * \log(n))$ 

// ideia do algoritmo:
// 1- ache 2 pontos a e b tal que, a e o ponto mais a
//    esquerda e b o ponto mais a direita do conjunto dado
// 2- a e b devem pertencer ao convex hull
// 3- desenhar uma linha ab, essa linha ira separar os
//    outros pontos em 2 conjuntos s1 (superior) e s2 (
//    inferior).
// 4- a e b pertencem aos dois conjuntos
// 5- agora para os conjuntos s1 e s2, achamos o convex
//    hull dos dois conjuntos.
// 6- para isso, ordene todos os pontos pela cordenada x
// 7- para cada ponto, se o ponto dado pertence ao
//    conjunto superior, verificamos o angulo formado pela
//    linha
//    que liga o penultimo ponto e o ultimo ponto do

```

```

    convex hull superior, com a linha que conecta o
//    ultimo ponto do convex hull e o ponto atual. Se o
//    angulo nao for no sentido horario,
//    removemos o ponto mais recente adicionado ao
//    convex hull superior, pois o ponto atual sera capaz
//    de conter o ponto anterior, uma vez que seja
//    adicionado ao convex hull.
// 8- fazer o mesmo para o conjunto inferior
// 9- ao final teremos o conjunto de pontos que formam o
//    convex hull dos n pontos

```
